Chapter 5: Differentiation

Author: Meng-Gen Tsai Email: plover@gmail.com

Exercise 5.1. Let f be defined for all real x, and suppose that

$$|f(x) - f(y)| \le (x - y)^2$$

for all real x and y. Prove that f is a constant.

Proof.

(1) Write

$$\left| \frac{f(x) - f(y)}{x - y} \right| \le |x - y|$$

if $x \neq y$.

(2) Given any $y \in \mathbb{R}$,

$$\left| \frac{f(x) - f(y)}{x - y} \right| \to 0 \text{ as } x \to y,$$

or |f'(y)| = 0.

(3) Or using ε - δ argument. Fix $y \in \mathbb{R}$. Given any $\varepsilon > 0$, there exists $\delta = \varepsilon > 0$ such that

$$\left| \frac{f(x) - f(y)}{x - y} - 0 \right| \le |x - y| < \delta = \varepsilon$$

whenever $|x - y| < \delta$. That is, |f'(y)| = 0.

(4) So f'(y) = 0 for any $y \in \mathbb{R}$. By Theorem 5.11 (b), f is a constant.

Exercise 5.2. Suppose f'(x) > 0 in (a,b). Prove that f is strictly increasing in (a,b), and let g be its inverse function. Prove that g is differentiable, and that

$$g'(f(x)) = \frac{1}{f'(x)}$$
 $(a < x < b).$

Proof. Let E = (a, b).

(1) Theorem 5.10 implies that for any $a there exists <math display="inline">\xi \in (p,q)$ such that

$$f(p) - f(q) = (p - q)f'(\xi).$$

Since $\xi \in (p,q) \subseteq E$, by assumption $f'(\xi) > 0$. Hence $f(p) - f(q) = (p-q)f'(\xi) < 0$ (here p-q < 0), or

if p < q. Therefore, f is strictly increasing in (a, b).

- (2) Show that f is one-to-one in E if f is strictly increasing in E. If f(p) = f(q), then it cannot be p > q or p < q ((1)). So that p = q, or f is injective.
- (3) Show that g is well-defined. Theorem 5.2 and Theorem 4.17.
- (4) Show that $g'(f(x)) = \frac{1}{f'(x)}$. Given $y \in f(E)$, say y = f(x) for some $x \in E$. Given any $s \in f(E)$ with $s \neq y$. Here s = f(t) for some $t \in E$ and $t \neq x$.

$$\lim_{s \to y} \frac{g(s) - g(y)}{s - y} = \lim_{f(t) \to f(x)} \frac{g(f(t)) - g(f(x))}{f(t) - f(x)}$$

$$= \lim_{t \to x} \frac{t - x}{f(t) - f(x)}$$

$$= \lim_{t \to x} \frac{1}{\frac{f(t) - f(x)}{t - x}}$$

$$= \frac{1}{f'(x)}. \qquad (f' > 0)$$

Here $s \to y$ if and only if $t \to x$ since both f and g are continuous and one-to-one. Hence g is differentiable and $g'(f(x)) = \frac{1}{f'(x)}$.

Exercise 5.3. Suppose g is a real function on \mathbb{R}^1 , with bounded derivative (say $|g'| \leq M$). Fix $\varepsilon > 0$, and define $f(x) = x + \varepsilon g(x)$. Prove that f is one-to-one if ε is small enough. (A set of admissible values of ε can be determined which depends only on M.)

Proof.

(1) Note that $f'(x) = 1 + \varepsilon g'(x)$ (Theorem 5.3). Since $|g'| \le M$,

$$1 - \varepsilon M < f'(x) < 1 + \varepsilon M$$
.

(2) Pick

$$\varepsilon = \frac{1}{M+1} > 0.$$

Thus,

$$f'(x) \ge \frac{1}{M+1} > 0.$$

By Exercise 5.2, f(x) is strictly increasing in \mathbb{R} or one-to-one in \mathbb{R} .

Exercise 5.4. If

$$C_0 + \frac{C_1}{2} + \dots + \frac{C_{n-1}}{n} + \frac{C_n}{n+1} = 0,$$

where C_0, \ldots, C_n are real constants, prove that the equation

$$C_0 + C_1 x + \dots + C_{n-1} x^{n-1} + C_n x^n = 0$$

has at least one real root between 0 and 1.

Proof. Let

$$g(x) = C_0 x + \frac{C_1}{2} x^2 + \dots + \frac{C_{n-1}}{n} x^n + \frac{C_n}{n+1} x^{n+1} \in \mathbb{R}[x].$$

Then g(0) = g(1) = 0, and $g'(x) = C_0 + C_1 x + \dots + C_{n-1} x^{n-1} + C_n x^n$. By the mean value theorem (Theorem 5.10), there exists a point $\xi \in (0,1)$ at which

$$g(1) - g(0) = g'(\xi)(1 - 0),$$

or $g'(\xi)=0$. That is, there exists a real root $x=\xi$ between 0 and 1 at which $C_0+C_1x+\cdots+C_{n-1}x^{n-1}+C_nx^n=0$. \square

Exercise 5.5. Suppose f is defined and differentiable for every x > 0, and $f'(x) \to 0$ as $x \to +\infty$. Put g(x) = f(x+1) - f(x). Prove that $g(x) \to 0$ as $x \to +\infty$.

Proof. Given any x > 0. Since f is differentiable for every x > 0, f is differentiable on [x, x+1]. By Theorem 5.2 and Theorem 5.10 (the mean value theorem), there is a point $\xi \in (x, x+1)$ at which

$$f(x+1) - f(x) = [(x+1) - x]f'(\xi)$$

or

$$g(x) = f'(\xi).$$

As $x \to +\infty$, $\xi \to +\infty$. Hence

$$\lim_{x \to +\infty} g(x) = \lim_{\xi \to +\infty} f'(\xi) = 0.$$

Exercise 5.6. Suppose

- (a) f is continuous for $x \ge 0$,
- (b) f'(x) exists for x > 0,
- (c) f(0) = 0,
- (d) f' is monotonically increasing.

Put

$$g(x) = \frac{f(x)}{r} \qquad (x > 0)$$

and prove that g is monotonically increasing.

Proof.

(1) It suffices to show that $g'(x) \ge 0$ for x > 0 (Theorem 5.11(a)), that is, to show that

$$g'(x) = \frac{xf'(x) - f(x)}{x^2} \ge 0$$
 $(x > 0),$

or

$$xf'(x) - f(x) \ge 0 \qquad (x > 0)$$

since $x^2 > 0$ for all nonzero x.

(2) Given x>0. By (a)(b), we apply the mean value theorem (Theorem 5.10) on f to get

$$f(x) - f(0) = (x - 0)f'(\xi)$$

for some $\xi \in (0, x)$. By (c),

$$f(x) = xf'(\xi).$$

By (d),

$$f(x) = xf'(\xi) \le xf'(x).$$

Hence $xf'(x) - f(x) \ge 0$, or g is monotonically increasing.

Note. g is increasing strictly if f is increasing strictly.

Exercise 5.7. Suppose f'(x), g'(x) exist, $g'(x) \neq 0$, and f(x) = g(x) = 0. Prove that

$$\lim_{t \to x} \frac{f(t)}{g(t)} = \frac{f'(x)}{g'(x)}.$$

(This holds also for complex functions.)

Proof.

$$\frac{f'(t)}{g'(t)} = \frac{\lim_{t \to x} \frac{f(t) - f(x)}{t - x}}{\lim_{t \to x} \frac{g(t) - g(x)}{t - x}}$$

$$= \lim_{t \to x} \frac{\frac{f(t) - f(x)}{t - x}}{\frac{f(t) - f(x)}{t - x}}$$
(Both limits exist and $g' \neq 0$)
$$= \lim_{t \to x} \frac{f(t)}{g(t)}.$$
($f(x) = g(x) = 0$)

This proof is also true for complex functions. \Box

Exercise 5.8. Suppose f'(x) is continuous on [a,b] and $\varepsilon > 0$. Prove that there exists $\delta > 0$ such that

 $\left| \frac{f(t) - f(x)}{t - x} - f'(x) \right| < \varepsilon$

whenever $0 < |t - x| < \delta$, $a \le x \le b$, $a \le t \le b$. (This could be expressed by saying f is uniformly differentiable on [a,b] if f' is continuous on [a,b].) Does this hold for vector-valued functions too?

Proof.

(1) Since f'(x) is continuous on a compact set [a, b], f'(x) is uniformly continuous on [a, b]. So given any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$|f'(t) - f'(x)| < \varepsilon$$

whenever $0 < |t - x| < \delta$, $a \le x \le b$, $a \le t \le b$.

(2) For such t < x in (1), by the mean value theorem (Theorem 5.10), there exists a point $\xi \in (t, x)$ at which

$$f'(\xi) = \frac{f(t) - f(x)}{t - x}.$$

Note that ξ is also satisfying $0<|t-\xi|<|t-x|<\delta$ and $a\leq \xi\leq b$. Hence by (1) we also have

$$|f'(\xi) - f'(x)| < \varepsilon,$$

or

$$\left| \frac{f(t) - f(x)}{t - x} - f'(x) \right| < \varepsilon.$$

(3) Suppose $\mathbf{f}'(x)$ is continuous on [a,b] and $\varepsilon > 0$. Prove that there exists $\delta > 0$ such that

$$\left| \frac{\mathbf{f}(t) - \mathbf{f}(x)}{t - x} - \mathbf{f}'(x) \right| < \varepsilon$$

whenever $0 < |t - x| < \delta$, $a \le x \le b$, $a \le t \le b$.

(a) Write

$$\mathbf{f}(x) = (f_1(x), \dots, f_k(x)) \in \mathbb{R}^k.$$

By Remarks 5.16, $\mathbf{f}(x)$ is differentiable at a point x if and only if each f_1, \ldots, f_k is differentiable at x. So that

$$\mathbf{f}'(x) = (f_1'(x), \dots, f_k'(x)) \in \mathbb{R}^k.$$

By Theorem 4.10, $\mathbf{f}'(x)$ is continuous if and only if each f_1, \ldots, f_k is continuous.

(b) Similar to (1)(2), Since $f_i'(x)$ is continuous on a compact set [a,b] where $1 \leq i \leq k$, $f_i'(x)$ is uniformly continuous on [a,b]. So given any $\varepsilon > 0$ there exists $\delta_i > 0$ such that

$$|f_i'(t) - f_i'(x)| < \frac{\varepsilon}{\sqrt{k}}$$

whenever $0<|t-x|<\delta_i,\ a\le x\le b,\ a\le t\le b.$ Take $\delta=\min_{1\le i\le k}\delta_i>0.$

(c) For such t < x in (1), by the mean value theorem (Theorem 5.10), there exists a point $\xi_i \in (t, x)$ at which

$$f_i'(\xi_i) = \frac{f_i(t) - f_i(x)}{t - r}.$$

Note that ξ_i is also satisfying $0<|t-\xi_i|<|t-x|<\delta$ and $a\leq \xi_i\leq b$. Hence by (1) we also have

$$|f_i'(\xi_i) - f_i'(x)| < \frac{\varepsilon}{\sqrt{k}},$$

or

$$\left| \frac{f_i(t) - f_i(x)}{t - x} - f_i'(x) \right| < \frac{\varepsilon}{\sqrt{k}}.$$

(d) Hence

$$\left|\frac{\mathbf{f}(t) - \mathbf{f}(x)}{t - x} - \mathbf{f}'(x)\right| = \left(\sum_{i=1}^{k} \left|\frac{f_i(t) - f_i(x)}{t - x} - f_i'(x)\right|^2\right)^{\frac{1}{2}} < \varepsilon.$$

Exercise 5.9. Let f be a continuous real function on \mathbb{R}^1 , of which it is known that f'(x) exists for all $x \neq 0$ and that $f'(x) \to 3$ as $x \to 0$. Dose it follow that f'(0) exists?

Proof.

(1) Show that f'(0) = 3. It is equivalent to show that

$$\lim_{x \to 0} \frac{f(x) - f(0)}{x - 0} = 3.$$

Write F(x) = f(x) - f(0) and G(x) = x - 0 on \mathbb{R}^1 . So that

$$\lim_{x \to 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \to 0} \frac{F(x)}{G(x)} = 0.$$

(2) Note that

$$\lim_{x \to 0} \frac{F'(x)}{G'(x)} = \lim_{x \to 0} \frac{f'(x)}{1} = 3.$$

(3) Since f is continuous on \mathbb{R}^1 , F is continuous on \mathbb{R}^1 . Hence

$$\lim_{x \to 0} F(x) = F(\lim_{x \to 0} x) = F(0) = 0.$$

Also, G is continuous on \mathbb{R}^1 implies that

$$\lim_{x \to 0} G(x) = G(\lim_{x \to 0} x) = G(0) = 0.$$

(4) Apply L'Hospital's rule (Theorem 5.13) to (2)(3), we have

$$\lim_{x \to 0} \frac{F(x)}{G(x)} = 3,$$

or
$$f'(0) = 3$$
.

Exercise 5.10. Suppose f and g are complex differentiable functions on (0,1), $f(x) \to 0$, $g(x) \to 0$, $f'(x) \to A$, $g'(x) \to B$ as $x \to 0$, where A and B are complex numbers, $B \neq 0$. Prove that

$$\lim_{x \to 0} \frac{f(x)}{g(x)} = \frac{A}{B}.$$

Compare with Example 5.18. (Hint:

$$\frac{f(x)}{g(x)} = \left(\frac{f(x)}{x} - A\right) \frac{x}{g(x)} + A \frac{x}{g(x)}.$$

Apply Theorem 5.13 to the real and imaginary parts of $\frac{f(x)}{x}$ and $\frac{g(x)}{x}$.)

 $Proof\ (Hint).$

(1) Write

$$f(x) = f_1(x) + if_2(x)$$

for $x \in (0,1)$, where both f_1 and f_2 are real functions. By Remarks 5.16, it is clear that

$$f'(x) = f_1'(x) + if_2'(x).$$

(2) Write

$$A = A_1 + iA_2$$

where both A_1 and A_2 are real numbers. Then as $x \to 0$, we have

- (a) $f(x) \to 0$ if and only if $f_1(x) \to 0$ and $f_2(x) \to 0$.
- (b) $f'(x) \to A$ if and only if $f'_1(x) \to A_1$ and $f'_2(x) \to A_2$.

Hence by L'Hospital's rule (Theorem 5.13),

$$\lim_{x \to 0} \frac{f_i(x)}{x} = \lim_{x \to 0} \frac{f_i'(x)}{1} = A_i$$

(i = 1, 2) or

$$\lim_{x \to 0} \frac{f(x)}{x} = \lim_{x \to 0} \frac{f_1(x) + if_2(x)}{x}$$

$$= \lim_{x \to 0} \frac{f_1(x)}{x} + i \lim_{x \to 0} \frac{f_2(x)}{x}$$

$$= A_1 + iA_2$$

$$= A.$$

Similarly,

$$\lim_{x \to 0} \frac{g(x)}{x} = B.$$

Note that $B \neq 0$, and thus

$$\lim_{x \to 0} \frac{x}{g(x)} = \frac{1}{B}.$$

(3) Hence

$$\begin{split} \lim_{x \to 0} \frac{f(x)}{g(x)} &= \lim_{x \to 0} \left[\left(\frac{f(x)}{x} - A \right) \frac{x}{g(x)} + A \frac{x}{g(x)} \right] \\ &= \lim_{x \to 0} \left(\frac{f(x)}{x} - A \right) \cdot \lim_{x \to 0} \frac{x}{g(x)} + \lim_{x \to 0} A \frac{x}{g(x)} \\ &= 0 \cdot \frac{1}{B} + \frac{A}{B} \\ &= \frac{A}{B}. \end{split}$$

(4) Compare with Example 5.18. Define f(x) = x and $g(x) = x + x^2 \exp\left(\frac{i}{x^2}\right)$ as in Example 5.18. Note that $f(x) \to 0$, $g(x) \to 0$, $f'(x) \to 1$ and $g'(x) \to \infty$ as $x \to 0$. By Example 5.18

$$\lim_{x \to 0} \frac{f(x)}{g(x)} = 1 \neq 0 = \frac{1}{\infty} = \lim_{x \to 0} \frac{A}{B}.$$

Exercise 5.11. Suppose f is defined in a neighborhood of x, and suppose f''(x) exists. Show that

$$\lim_{h \to 0} \frac{f(x+h) + f(x-h) - 2f(x)}{h^2} = f''(x).$$

Show by an example that the limit may exist even if f''(x) dose not. (Hint: Use Theorem 5.13.)

Proof (Theorem 5.13).

(1) Write F(h) = f(x+h) + f(x-h) - 2f(x) and $G(h) = h^2$. It is equivalent to show that

$$\lim_{h \to 0} \frac{F(h)}{G(h)} = f''(x).$$

We might apply Theorem 5.13 (L'Hospital rule) to get it.

(2) Show that $\lim_{h\to 0} F(h) = 0$ and $\lim_{h\to 0} G(h) = 0$. It is clear that $\lim_{h\to 0} G(h) = \lim_{h\to 0} h^2 = 0$ since $x\mapsto x^2$ is continuous on \mathbb{R}^1 . Besides, since f is continuous at x (by applying Theorem 5.2 twice),

$$\lim_{h \to 0} F(h) = f(x) + f(x) - 2f(x) = 0.$$

(3) Show that

$$\lim_{h \to 0} \frac{F'(h)}{G'(h)} = \lim_{h \to 0} \frac{f'(x+h) - f'(x-h)}{2h}$$

is well-defined. Since f''(x) exists in a neighborhood B(x;r) of x (where r > 0), f'(x) exists and is continuous in B(x;r) (Theorem 5.2). As $0 < |h| < \frac{r}{2}$,

$$x + h \in B\left(x + h; \frac{r}{2}\right) \subseteq B(x; r)$$

and

$$x - h \in B\left(x - h; \frac{r}{2}\right) \subseteq B(x; r).$$

So f'(x+h) and f'(x-h) exist in B(x;r) as $0<|h|<\frac{r}{2}$. Hence

$$\lim_{h \to 0} \frac{F'(h)}{G'(h)} = \lim_{h \to 0} \frac{f'(x+h) - f'(x-h)}{2h}$$

is well-defined (Theorem 5.3 and Theorem 5.5 (the chain rule)).

(4) Show that

$$\lim_{h \to 0} \frac{f'(x+h) - f'(x-h)}{2h} = f''(x).$$

Since f''(x) exists, by definition

$$\lim_{h \to 0} \frac{f'(x+h) - f'(x)}{h} = f''(x)$$

and

$$\lim_{h \to 0} \frac{f'(x-h) - f'(x)}{-h} = f''(x).$$

Sum up two expressions to get

$$2f''(x) = \lim_{h \to 0} \frac{f'(x-h) - f'(x-h)}{h}.$$

- (5) By (2)(3)(4) and Theorem 5.13 (L'Hospital rule), the result is established.
- (6) Given f(x) = x|x| on \mathbb{R}^1 . Show that

$$\lim_{h \to 0} \frac{f(h) + f(-h) - 2f(0)}{h^2} = 0$$

but f''(x) does not exist at x = 0. Clearly,

$$\lim_{h \to 0} \frac{f(h) + f(-h) - 2f(0)}{h^2} = \lim_{h \to 0} \frac{h|h| + (-h)| - h| - 2 \cdot 0}{h^2}$$

$$= \lim_{h \to 0} \frac{h|h| - h|h| - 0}{h^2}$$

$$= \lim_{h \to 0} 0$$

$$= 0$$

But f''(x) does not exist by Exercise 5.12.

Exercise 5.12. If $f(x) = |x|^3$, compute f'(x), f''(x) for all real x, and show that $f^{(3)}(0)$ does not exist.

Proof.

(1) Write

$$f(x) = \begin{cases} x^3 & (x \ge 0), \\ -x^3 & (x \le 0). \end{cases}$$

(2) Show that f'(x) = 3x|x|. It is trivial that

$$f'(x) = \begin{cases} 3x^2 & (x > 0), \\ -3x^2 & (x < 0). \end{cases}$$

Note that

$$\lim_{x \to 0} f'(x) = 0.$$

Apply the same argument in Exercise 5.9, we have

$$f'(0) = 0.$$

Hence f' exists and f'(x) = 3x|x| for any $x \in \mathbb{R}$.

(3) Show that f''(x) = 6|x|. Similar to (2).

$$f''(x) = \begin{cases} 6x & (x > 0), \\ -6x & (x < 0). \end{cases}$$

Note that

$$\lim_{x \to 0} f''(x) = 0.$$

Apply the same argument in Exercise 5.9, we have

$$f''(0) = 0.$$

Hence f'' exists and f''(x) = 6|x| for any $x \in \mathbb{R}$.

(4) Show that $f^{(3)}(0)$ does not exist.

$$f'''(x) = \begin{cases} 6 & (x > 0), \\ -6 & (x < 0). \end{cases}$$

There are some proofs for showing that $f^{(3)}(0)$ does not exist.

(a) Since

$$\lim_{t \to 0+} \frac{f''(t) - f''(0)}{t - 0} = \lim_{t \to 0+} \frac{6t}{t} = 6$$

and

$$\lim_{t\to 0-}\frac{f''(t)-f''(0)}{t-0}=\lim_{t\to 0-}\frac{-6t}{t}=-6,$$

 $f^{(3)}(0)$ does not exist.

(b) (Reductio ad absurdum) If f were differentiable on \mathbb{R}^1 , then

$$\lim_{t \to 0+} f'''(t) = 6$$

and

$$\lim_{t \to 0-} f'''(t) = -6,$$

or f''' has a simple discontinuity at x=0, contrary to Corollary to Theorem 5.12.

Note. Given k > 0. We can construct one real function f on \mathbb{R}^1 , say

$$f(x) = \begin{cases} |x|^k & (k \text{ is odd}), \\ x|x|^{k-1} & (k > 0 \text{ is even}), \end{cases}$$

such that all $f^{(0)}(0) = \cdots = f^{(k-1)}(0) = 0$ exist but $f^{(k)}(0)$ does not exist.

Exercise 5.13. Suppose a and c are real numbers, c > 0, and f is defined on [-1,1] by

$$f(x) = \begin{cases} x^a \sin(x^{-c}) & (if \ x \neq 0), \\ 0 & (if \ x = 0). \end{cases}$$

Prove the following statements:

- (a) f is continuous if and only if a > 0.
- (b) f'(0) exists if and only if a > 1.
- (c) f' is bounded if and only if $a \ge 1 + c$.
- (d) f' is continuous if and only if a > 1 + c.
- (e) f''(0) exists if and only if a > 2 + c.
- (f) f'' is bounded if and only if a > 2 + 2c.
- (g) f'' is continuous if and only if a > 2 + 2c.

Note that f is not well-defined as a real function if x < 0. Hence we modify the definition of f for the case x < 0:

$$f(x) = \begin{cases} |x|^a \sin(|x|^{-c}) & \text{(if } x \neq 0), \\ 0 & \text{(if } x = 0). \end{cases}$$

Proof of (a).

(1) Since $|x|^a \sin{(|x|^{-c})}$ is continuous on $\mathbb{R}^1 - \{0\}$, f is continuous if and only if

$$\lim_{x \to 0} |x|^a \sin(|x|^{-c}) = 0.$$

(2) Given a > 0. Show that

$$\lim_{x \to 0} |x|^a \sin(|x|^{-c}) = 0.$$

Since $|x|^a \to 0$ as $x \to 0$ and $|\sin(|x|^{-c})|$ is bounded by 1, the limit $\lim |x|^a \sin(|x|^{-c})$ exists and is equal to 0.

(3) Given a = 0. Show that

$$\lim_{x \to 0} |x|^a \sin(|x|^{-c}) = \lim_{x \to 0} \sin(|x|^{-c})$$

does not exist although $|x|^a \sin(|x|^{-c}) = \sin(|x|^{-c})$ is bounded on $[-1, 1] - \{0\}$.

(a) Take $x_n = \left(\frac{\pi}{2} + 2n\pi\right)^{-\frac{1}{c}} \neq 0$ for $n = 1, 2, 3, \ldots$ The sequence $\{x_n\}$ converges to 0, and

$$\lim_{n \to \infty} f(x_n) = \lim_{n \to \infty} \sin(|x_n|^{-c}) = \lim_{n \to \infty} 1 = 1.$$

(b) Similarly, take $y_n=(2n\pi)^{-\frac{1}{c}}\neq 0$ for $n=1,2,3,\ldots$ The sequence $\{y_n\}$ converges to 0, and

$$\lim_{n \to \infty} f(y_n) = 0.$$

- (c) By (a)(b), $\lim_{x\to 0} |x|^a \sin(|x|^{-c})$ does not exist (Theorem 4.2).
- (d) Clearly, $|\sin(|x|^{-c})| \le 1$ as $\sin(|x|^{-c})$ is well-defined.
- (4) Given a < 0. Show that

$$\lim_{x\to 0} |x|^a \sin\left(|x|^{-c}\right)$$

does not exist. Similar to (3), we take the same $\{x_n\}$ and $\{y_n\}$ as (3) to get the similar result:

$$\lim_{n \to \infty} f(x_n) = \infty,$$
$$\lim_{n \to \infty} f(y_n) = 0.$$

 $n \to \infty$

(5) By (2)(3)(4), f is continuous if and only if a > 0.

By Theorem 4.2, $\lim_{x\to 0} |x|^a \sin(|x|^{-c})$ does not exist.

Proof of (b).

(1) By definition,

$$f'(0) = \lim_{x \to 0} \frac{f(x) - f(0)}{x - 0} = \lim_{x \to 0} \operatorname{sgn}(x) |x|^{a - 1} \sin(|x|^{-c}).$$

Here sgn(x) is the sign function defined by

$$\operatorname{sgn}(x) = \begin{cases} 1 & (x > 0), \\ 0 & (x = 0), \\ -1 & (x < 0). \end{cases}$$

(2) Similar to (2)(3)(4) in the proof of (a), f'(0) = 0 exists if and only if a-1>0.

Proof of (c).

- (1) Write $E = [-1, 1] \{0\}$. f' is bounded if and only if f'(0) exists and f' is bounded on E.
- (2) Given any $x \in E$,

$$f'(x) = \operatorname{sgn}(x) \left(a|x|^{a-1} \sin(|x|^{-c}) + |x|^a \cos(|x|^{-c})(-c)|x|^{-c-1} \right)$$

= $\operatorname{sgn}(x)|x|^{a-c-1} \left(a|x|^c \sin(|x|^{-c}) - c \cos(|x|^{-c}) \right).$

- (3) Given $a-c-1 \ge 0$. Show that f' is bounded on E. Since $\operatorname{sgn}(x)$ is bounded by 1 on E, $|x|^{a-c-1}$ is bounded by 1 on E and $a|x|^c \sin(|x|^{-c}) c\cos(|x|^{-c})$ is bounded by |a| + |c| on E, f' is bounded on E.
- (4) Given a-c-1<0. Show that f' is unbounded on E. Take $x_n=(2n\pi)^{-\frac{1}{c}}\neq 0$ for $n=1,2,3,\ldots$ The sequence $\{x_n\}$ converges to 0, and

$$\lim_{n \to \infty} f'(x_n) = \lim_{n \to \infty} -c(2n\pi)^{-\frac{a-c-1}{c}} = -\infty.$$

(5) By (b), f'(0) exists if and only if a > 1. By (3)(4), f' is bounded on E if and only if $a - c - 1 \ge 0$. Since c > 0, f' is bounded on [-1, 1] if and only if $a - c - 1 \ge 0$.

Proof of (d). Similar to the proof of (a).

(1) Write $E = [-1, 1] - \{0\}$. By (b)(c),

$$f'(x) = \begin{cases} 0 & \text{if } x = 0, \\ \operatorname{sgn}(x)|x|^{a-c-1} \left(a|x|^c \sin(|x|^{-c}) - c\cos(|x|^{-c}) \right) & \text{if } x \in E. \end{cases}$$

Clearly, f' is continuous on E. Hence, f' is continuous if and only if $\lim_{x\to 0} f'(x) = f'(0) = 0$.

(2) Given a-c-1>0. Show that $\lim_{x\to 0} f'(x)=0$. Since $|x|^{a-c-1}\to 0$ as $x\to 0$, $\operatorname{sgn}(x)$ is bounded by 1 on E, and $a|x|^c \sin(|x|^{-c})-c\cos(|x|^{-c})$ is bounded by |a|+|c| on E,

$$\operatorname{sgn}(x)|x|^{a-c-1} \left(a|x|^c \sin(|x|^{-c}) - c\cos(|x|^{-c}) \right) \to 0$$

as $x \to 0$. The result is established.

- (3) Given a-c-1=0. Show that $\lim_{x\to 0} f'(x)$ does not exist.
 - (a) Take $x_n = \left(\frac{\pi}{2} + 2n\pi\right)^{-\frac{1}{c}} \neq 0$ for $n = 1, 2, 3, \ldots$ The sequence $\{x_n\}$ converges to 0, and

$$\lim_{n \to \infty} f'(x_n) = \lim_{n \to \infty} \operatorname{sgn}(x_n) \left(a|x_n|^c \sin(|x_n|^{-c}) - c \cos(|x_n|^{-c}) \right)$$
$$= \lim_{n \to \infty} \frac{a}{\frac{\pi}{2} + 2n\pi}$$
$$= 0.$$

(b) Similarly, take $y_n=(2n\pi)^{-\frac{1}{c}}\neq 0$ for $n=1,2,3,\ldots$ The sequence $\{y_n\}$ converges to 0, and

$$\lim_{n \to \infty} f'(y_n) = \lim_{n \to \infty} \operatorname{sgn}(y_n) \left(a|y_n|^c \sin(|y_n|^{-c}) - c\cos(|y_n|^{-c}) \right)$$
$$= \lim_{n \to \infty} -c$$
$$= -c \neq 0$$

- (c) By (a)(b), $\lim_{x\to 0} f'(x)$ does not exist (Theorem 4.2).
- (4) Given a-c-1 < 0. Show that $\lim_{x\to 0} f'(x)$ does not exist. It is the same as (4) in the proof of (c).
- (5) By (2)(3)(4), f' is continuous if and only if $\lim_{x\to 0} f'(x) = 0$ if and only if a-c-1>0.

Proof of (e). Similar to the proof of (b).

(1) Write $E = [-1, 1] - \{0\}$. By the proof of (d),

$$f'(x) = \begin{cases} 0 & \text{if } x = 0, \\ \operatorname{sgn}(x)|x|^{a-c-1} \left(a|x|^c \sin(|x|^{-c}) - c\cos(|x|^{-c}) \right) & \text{if } x \in E. \end{cases}$$

By definition

$$f''(0) = \lim_{x \to 0} \frac{f'(x) - f'(0)}{x - 0}$$

= $\lim_{x \to 0} |x|^{a - c - 2} (a|x|^c \sin(|x|^{-c}) - c\cos(|x|^{-c})).$

(Here $sgn(x)^2 = 1$ if $x \neq 0$.)

(2) Similar to (2)(3)(4) in the proof of (d), f''(0) = 0 exists if and only if (a-c-1)-1 = a-c-2 > 0.

Proof of (f). Similar to the proof of (c).

- (1) Write $E = [-1, 1] \{0\}$. f'' is bounded if and only if f''(0) exists and f'' is bounded on E.
- (2) Given any $x \in E$,

$$f''(x) = |x|^{a-2c-2} \cdot \left[(a(a-1)|x|^{2c} - c^2) \sin(|x|^{-c}) - c(2a-c-1)|x|^c \cos(|x|^{-c}) \right].$$

(3) Given $a-2c-2 \ge 0$. Show that f'' is bounded on E. Since $|x|^{a-2c-2}$ is bounded by 1 on E and

$$\left| (a(a-1)|x|^{2c} - c^2) \sin(|x|^{-c}) - c(2a-c-1)|x|^c \cos(|x|^{-c}) \right|$$

$$\leq |a(a-1)| + |c^2| + |c(2a-c-1)|$$

is bounded on E, f'' is bounded on E.

(4) Given a-2c-2<0. Show that f'' is unbounded on E. Take $x_n=\left(\frac{\pi}{2}+2n\pi\right)^{-\frac{1}{c}}\neq 0$ for $n=1,2,3,\ldots$ The sequence $\{x_n\}$ converges to 0, and

$$\lim_{n \to \infty} f''(x_n)$$

$$= \lim_{n \to \infty} \underbrace{\left(a(a-1)\left(\frac{\pi}{2} + 2n\pi\right)^{-2} - c^2\right)}_{\rightarrow -c^2 \neq 0} \underbrace{\left(\frac{\pi}{2} + 2n\pi\right)^{-\frac{a-2c-2}{c}}}_{\rightarrow \infty}$$

(5) By (e), f''(0) exists if and only if a-c-2>0. By (3)(4), f'' is bounded on E if and only if $a-2c-2\geq 0$. Since c>0, f'' is bounded on [-1,1] if and only if $a-2c-2\geq 0$.

Proof of (g). Similar to the proof of (a) or (d).

(1) Write $E = [-1, 1] - \{0\}$. By (e)(f),

$$f''(x) = \begin{cases} 0 & \text{if } x = 0, \\ |x|^{a-2c-2} \left[(a(a-1)|x|^{2c} - c^2) \sin(|x|^{-c}) - c(2a-c-1)|x|^c \cos(|x|^{-c}) \right]. & \text{if } x \in E. \end{cases}$$

Clearly, f'' is continuous on E. Hence, f'' is continuous if and only if $\lim_{x\to 0} f''(x) = f''(0) = 0$.

(2) Given a-2c-2>0. Show that $\lim_{x\to 0}f''(x)=0$. Since $|x|^{a-2c-2}\to 0$ as $x\to 0$ and

$$(a(a-1)|x|^{2c}-c^2)\sin(|x|^{-c})-c(2a-c-1)|x|^c\cos(|x|^{-c})$$

is bounded by $|a(a-1)| + |c^2| + |c(2a-c-1)|$ on E,

$$|x|^{a-2c-2} \cdot \left[(a(a-1)|x|^{2c} - c^2) \sin(|x|^{-c}) - c(2a-c-1)|x|^c \cos(|x|^{-c}) \right] \to 0$$

as $x \to 0$. The result is established.

- (3) Given a-2c-2=0. Show that $\lim_{x\to 0} f''(x)$ does not exist.
 - (a) Take $x_n = \left(\frac{\pi}{2} + 2n\pi\right)^{-\frac{1}{c}} \neq 0$ for $n = 1, 2, 3, \ldots$ The sequence $\{x_n\}$ converges to 0, and

$$\lim_{n \to \infty} f''(x_n)$$

$$= \lim_{n \to \infty} (a(a-1)|x_n|^{2c} - c^2) \sin(|x_n|^{-c}) - c(2a-c-1)|x_n|^c \cos(|x_n|^{-c})$$

$$= \lim_{n \to \infty} \frac{a(a-1)}{\left(\frac{\pi}{2} + 2n\pi\right)^2} - c^2$$

$$= -c^2$$

(b) Similarly, take $y_n=\left(\frac{3\pi}{2}+2n\pi\right)^{-\frac{1}{c}}\neq 0$ for $n=1,2,3,\ldots$ The sequence $\{y_n\}$ converges to 0, and

$$\lim_{n \to \infty} f''(y_n)$$

$$= \lim_{n \to \infty} (a(a-1)|y_n|^{2c} - c^2) \sin(|y_n|^{-c}) - c(2a-c-1)|y_n|^c \cos(|y_n|^{-c})$$

$$= \lim_{n \to \infty} -\frac{a(a-1)}{\left(\frac{3\pi}{2} + 2n\pi\right)^2} + c^2$$

$$= c^2.$$

- (c) By (a)(b), $\lim_{x\to 0} f''(x)$ does not exist (Theorem 4.2).
- (4) Given a 2c 2 < 0. Show that $\lim_{x\to 0} f''(x)$ does not exist. It is the same as (4) in the proof of (f).
- (5) By (2)(3)(4), f'' is continuous if and only if $\lim_{x\to 0} f''(x) = 0$ if and only if a 2c 2 > 0.

Exercise 5.14. Let f be a differentiable real function defined in (a,b). Prove that f is convex if and only if f' is monotonically increasing. Assume next f''(x) exists for every $x \in (a,b)$, and prove that f is convex if and only if $f''(x) \geq 0$ for all $x \in (a,b)$.

Proof.

- (1) Show that f' is monotonically increasing if f is convex.
 - (a) Since f is convex, by definition (Exercise 4.23)

$$f(\lambda x + (1 - \lambda)y) \le \lambda f(x) + (1 - \lambda)f(y)$$

whenever a < x < b, a < y < b, $0 < \lambda < 1$.

(b) As $x \neq y$, we have

$$f(y) - f(x) \ge \frac{f(x + \lambda(y - x)) - f(x)}{\lambda}$$
$$= \frac{f(x + \lambda(y - x)) - f(x)}{\lambda(y - x)} \cdot (y - x)$$

and let $\lambda \to 0$ to get

$$f(y) - f(x) \ge f'(x)(y - x)$$

(since f'(x) exists). Similarly, we have

$$f(x) - f(y) \ge f'(y)(x - y).$$

(c) Given any y > x, we have

$$f'(y)(y-x) > f(y) - f(x) > f'(x)(y-x).$$

Hence $f'(y) \ge f'(x)$ whenever y > x, or f' is monotonically increasing.

- (2) Show that f is convex if f' is monotonically increasing. Given any y > x and any $0 < \lambda < 1$.
 - (a) By Theorem 5.10 (the mean value theorem), there is a point $x < \xi < y$ such that

$$f(y) - f(x) = f'(\xi)(y - x).$$

Since f' is monotonically increasing,

$$f'(y)(y-x) \ge f(y) - f(x) \ge f'(x)(y-x).$$

(b) Write $z = \lambda x + (1 - \lambda)y$. Hence

$$f(y) - f(z) \ge f'(z)(y - z),$$

$$f(z) - f(x) < f'(z)(z - x),$$

or

$$f(y) \ge f(z) + f'(z)(y - z),$$

$$f(x) \ge f(z) + f'(z)(x - z),$$

or

$$\lambda f(x) + (1 - \lambda)f(y) \ge \lambda [f(z) + f'(z)(x - z)]$$

$$+ (1 - \lambda)[f(z) + f'(z)(y - z)]$$

$$= f(z)$$

$$= f(\lambda x + (1 - \lambda)y).$$

Hence f is convex.

(3) Show that $f''(x) \ge 0$ if f is convex and f'' exists. By (1), f' is monotonically increasing since f is convex. Given any $x \ne y$, we have

$$\frac{f'(y) - f'(x)}{y - x} \ge 0.$$

Let $y \to x$, we have $f''(x) \ge 0$ if f'' exists.

(4) Show that f is convex if f'' exists and $f''(x) \ge 0$. By Theorem 5.11(a), f' is monotonically increasing. By (2), f is convex.

Exercise 5.15 (Landau-Kolmogorov inequality on the half-line). Suppose $a \in \mathbb{R}^1$, f is a twice-differentiable real function on (a, ∞) , and M_0 , M_1 , M_2 are the least upper bounds of |f(x)|, |f'(x)|, |f''(x)|, respectively, on (a, ∞) . Prove that

$$M_1^2 \le 4M_0M_2$$
.

(Hint: If h > 0, Taylor's theorem shows that

$$f'(x) = \frac{1}{2h}[f(x+2h) - f(x)] - hf''(\xi)$$

for some $\xi \in (x, x + 2h)$. Hence

$$|f'(x)| \le hM_2 + \frac{M_0}{h}$$
.)

To show that $M_1^2 = 4M_0M_2$ can actually happen, take a = -1, define

$$f(x) = \begin{cases} 2x^2 - 1 & (-1 < x < 0), \\ \frac{x^2 - 1}{x^2 + 1} & (0 \le x < \infty), \end{cases}$$

and show that $M_0=1,\ M_1=4,\ M_2=4.$ Does $M_1^2\leq 4M_0M_2$ hold for vector-valued functions too?

Note.

(1) Write

$$M_1 \le 2M_0^{\frac{1}{2}} M_2^{\frac{1}{2}}.$$

2 is called the Landau-Kolmogorov constant, which is the best possible by the above example.

(2) In general, suppose $a \in \mathbb{R}^1$, f is a nth differentiable real function on (a, ∞) , and M_0 , M_k , M_n are the least upper bounds of |f(x)|, $|f^{(k)}(x)|$, $|f^{(n)}(x)|$, respectively, on (a, ∞) where $1 \le k < n$. Then

$$M_k \le C(n,k) M_0^{1-\frac{k}{n}} M_n^{\frac{k}{n}}.$$

Proof.

(1) Consider some trivial cases.

- (a) If $M_0 = 0$, then f(x) = 0 on $(a, +\infty)$. So that f'(x) = f''(x) = 0 on $(a, +\infty)$, or $M_1 = M_2 = 0$. The inequality holds.
- (b) If $M_2 = 0$, then f''(x) = 0 on $(a, +\infty)$. So that $f'(x) = \alpha$ for some constant $\alpha \in \mathbb{R}^1$ (Theorem 5.11(b)), and $f(x) = \alpha x + \beta$ for some constant $\beta \in \mathbb{R}^1$ (by applying Theorem 5.11(b) to $x \mapsto f(x) \alpha x$). Hence $M_1 = |\alpha|$ and

$$M_0 = \begin{cases} +\infty & (\alpha \neq 0), \\ |\beta| & (\alpha = 0). \end{cases}$$

In any case, the inequality holds.

- (c) If $M_0 = +\infty$ and $M_2 \neq 0$, there is nothing to do.
- (d) If $M_2 = +\infty$ and $M_0 \neq 0$, there is nothing to do.
- (2) By (1), we suppose that $0 < M_0 < +\infty$ and $0 < M_2 < +\infty$. Given $x \in (a, +\infty)$ and h > 0. By Taylor's theorem (Theorem 5.15):

$$f(x+2h) = f(x) + 2hf'(x) + 2h^2f''(\xi)$$

for some $\xi \in (x, x + 2h) \subseteq (a, +\infty)$. Thus

$$2h|f'(x)| \le |f(x+2h)| + |f(x)| + 2h^2|f''(\xi)|$$

$$\le 2M_0 + 2h^2M_2,$$

$$|f'(x)| \le \frac{M_0}{h} + hM_2$$

holds for all h > 0. In particular, take

$$h = \sqrt{\frac{M_0}{M_2}}$$

to get

$$|f'(x)| \le 2\sqrt{M_0 M_2}$$
.

Thus $2\sqrt{M_0M_2}$ is an upper bound of |f'(x)| for all $x \in (a, +\infty)$. Hence

$$M_1 \leq 2\sqrt{M_0 M_2}$$

or

$$M_1^2 \le 4M_0M_2$$
.

(3) Define

$$f(x) = \begin{cases} 2x^2 - 1 & (-1 < x < 0), \\ \frac{x^2 - 1}{x^2 + 1} & (0 \le x < \infty). \end{cases}$$

Show that $M_0 = 1$, $M_1 = 4$, $M_2 = 4$. Similar to Exercise 5.12,

$$f'(x) = \begin{cases} 4x & (-1 < x \le 0), \\ \frac{4x}{(x^2+1)^2} & (0 \le x < \infty). \end{cases}$$

(Here $\lim_{x\to 0+} f'(x) = 0$ and $\lim_{x\to 0-} f'(x) = 0$. So f'(0) = 0 by Exercise 5.9.) Also,

$$f''(x) = \begin{cases} 4 & (-1 < x \le 0), \\ \frac{-12x^2 + 4}{(x^2 + 1)^3} & (0 \le x < \infty). \end{cases}$$

(Here $\lim_{x\to 0+} f''(x) = 4$ and $\lim_{x\to 0-} f''(x) = 4$. So f''(0) = 4 by Exercise 5.9.) Hence, $M_0 = 1$, $M_1 = 4$, $M_2 = 4$.

(4) Given

$$\mathbf{f}(x) = (f_1(x), \dots, f_k(x))$$

be a twice-differentiable vector-valued function from (a, ∞) to \mathbb{R}^k . and M_0 , M_1 , M_2 are the least upper bounds of $|\mathbf{f}(x)|$, $|\mathbf{f}'(x)|$, $|\mathbf{f}''(x)|$, respectively, on (a, ∞) . Show that

$$M_1^2 \le 4M_0M_2$$
.

Similar to (1), we suppose that $0 < M_0 < +\infty$ and $0 < M_2 < +\infty$. Given any $\mathbf{v} = (v_1, \dots, v_k) \in \mathbb{R}^k$, $\mathbf{v} \cdot \mathbf{f}$ is a twice-differentiable real function on (a, ∞) . Similar to (2), Given $x \in (a, +\infty)$ and h > 0. By Taylor's theorem (Theorem 5.15):

$$(\mathbf{v} \cdot \mathbf{f})(x+2h) = (\mathbf{v} \cdot \mathbf{f})(x) + 2h(\mathbf{v} \cdot \mathbf{f})'(x) + 2h^2(\mathbf{v} \cdot \mathbf{f})''(\xi)$$

for some $\xi \in (x, x+2h) \subseteq (a, +\infty)$. Thus by the Schwarz inequality (Theorem 1.37(d))

$$2h|(\mathbf{v}\cdot\mathbf{f})'(x)| \leq |(\mathbf{v}\cdot\mathbf{f})(x+2h)| + |(\mathbf{v}\cdot\mathbf{f})(x)| + 2h^{2}|(\mathbf{v}\cdot\mathbf{f})''(\xi)|$$

$$\leq |\mathbf{v}||\mathbf{f}(x+2h)| + |\mathbf{v}||\mathbf{f}(x)| + 2h^{2}|\mathbf{v}||\mathbf{f}''(\xi)|$$

$$\leq (2M_{0} + 2h^{2}M_{2})|\mathbf{v}|,$$

$$|(\mathbf{v}\cdot\mathbf{f})'(x)| \leq \left(\frac{M_{0}}{h} + hM_{2}\right)|\mathbf{v}|$$

holds for any \mathbf{v} and h > 0. In particular, we take

$$\mathbf{v} = \mathbf{f}'(y)$$

and

$$h = \sqrt{\frac{M_0}{M_2}}$$

to get

$$|\mathbf{f}'(x) \cdot \mathbf{f}'(y)| \le 2\sqrt{M_0 M_2} |\mathbf{f}'(y)| \le 2M_1 \sqrt{M_0 M_2}.$$

Note that x and y are arbitrary (in $(a, +\infty)$). In particular, we take x=y to get

$$|\mathbf{f}'(x)|^2 \le 2M_1 \sqrt{M_0 M_2}.$$

Thus $2M_1\sqrt{M_0M_2}$ is an upper bound of $|\mathbf{f}'(x)|^2$ for all $x \in (a, +\infty)$. Hence

$$M_1^2 \le 2M_1\sqrt{M_0M_2}$$

or

$$M_1^2 \le 4M_0M_2.$$

Supplement (Landau-Kolmogorov inequality on the real line). Suppose f is a twice-differentiable real function on $(-\infty, +\infty)$, and M_0 , M_1 , M_2 are the least upper bounds of |f(x)|, |f'(x)|, |f''(x)|, respectively, on $(-\infty, +\infty)$. Prove that

$$M_1^2 \le 2M_0M_2.$$

Proof.

- (1) Similar to (1) in Landau-Kolmogorov inequality on the half-line, we suppose that $0 < M_0 < +\infty$ and $0 < M_2 < +\infty$.
- (2) Similar to (2) in Landau-Kolmogorov inequality on the half-line. Given $x \in \mathbb{R}^1$ and h > 0. By Taylor's theorem (Theorem 5.15):

$$f(x+2h) = f(x) + 2hf'(x) + 2h^2f''(\xi_1)$$
 (I)

$$f(x-2h) = f(x) - 2hf'(x) + 2h^2f''(\xi_2)$$
 (II)

for some $\xi_1 \in (x, x+2h)$ and $\xi_2 \in (x, x-2h)$. So (I) subtracts (II):

$$f(x+2h) - f(x-2h) = 4hf'(x) + 2h^2f''(\xi_1) - 2h^2f''(\xi_2).$$

Thus

$$4h|f'(x)| \le |f(x+2h)| + |f(x-2h)| + 2h^2|f''(\xi_1)| + 2h^2|f''(\xi_2)|$$

$$\le 2M_0 + 4h^2M_2,$$

$$|f'(x)| \le \frac{M_0}{2h} + hM_2$$

holds for all h > 0. In particular, take

$$h = \sqrt{\frac{M_0}{2M_2}}$$

to get

$$|f'(x)| \le \sqrt{2M_0 M_2}.$$

Thus $\sqrt{2M_0M_2}$ is an upper bound of |f'(x)| for all $x \in \mathbb{R}^1$. Hence

$$M_1 \le \sqrt{2M_0M_2}$$

or

$$M_1^2 \le 2M_0M_2$$
.

Note.

(1) Write

$$M_1 \leq \sqrt{2} M_0^{\frac{1}{2}} M_2^{\frac{1}{2}}.$$

 $\sqrt{2}$ is called the Landau-Kolmogorov constant, which is the best possible.

(2) In general, suppose f is a nth differentiable real function on \mathbb{R}^1 , and M_0 , M_k , M_n are the least upper bounds of |f(x)|, $|f^{(k)}(x)|$, $|f^{(n)}(x)|$, respectively, on \mathbb{R}^1 where $1 \leq k < n$. Then

$$M_k \le C(n,k) M_0^{1-\frac{k}{n}} M_n^{\frac{k}{n}}.$$

Exercise 5.16. Suppose f is twice-differentiable on $(0,\infty)$, f'' is bounded on $(0,\infty)$, and $f(x) \to 0$ as $x \to \infty$. Prove that $f'(x) \to 0$ as $x \to \infty$. (Hint: Let $a \to \infty$ in Exercise 5.15.)

Proof.

- (1) Write $|f''| \leq M$ for some real M since f'' is bounded on $(0, \infty)$.
- (2) Given any a > 0. As in Exercise 5.15, define M_0, M_1, M_2 are the least upper bounds of |f(x)|, |f'(x)|, |f''(x)| on (a, ∞) . Note that $M_2 \leq M$ for any a > 0 (by (1)). So that

$$M_1^2 \le 4M_0M_2 \le 4MM_0$$

for any a > 0.

(3) By assumption, $M_0 \to 0$ as $a \to \infty$. (So given any $\varepsilon > 0$, there exists a real A such that

$$0 \le M_0 < \frac{\varepsilon}{4M+1}$$

whenever $a \geq A$. Hence

$$M_1^2 \le 4MM_0 \le 4M \cdot \frac{\varepsilon}{4M+1} < \varepsilon.$$

whenever $a \geq A$.) Therefore $M_1^2 \to 0$ as $a \to \infty$, or $f'(x) \to 0$ as $x \to \infty$.

Exercise 5.17. Suppose f is a real, three times differentiable function on [-1,1], such that

$$f(-1) = 0,$$
 $f(0) = 0,$ $f(1) = 1,$ $f'(0) = 0.$

Prove that $f^{(3)}(x) \geq 3$ for some $x \in (-1,1)$. Note that equality holds for $\frac{1}{2}(x^3+x^2)$. (Hint: Use Theorem 5.15, with $\alpha=0$ and $\beta=\pm 1$, to show that there exist $s\in (0,1)$ and $t\in (-1,0)$ such that

$$f^{(3)}(s) + f^{(3)}(t) = 6.$$

We can drop the assumption that f(0) = 0 actually.

Proof (Hint).

(1) Use Taylor's theorem (Theorem 5.15), with $\alpha = 0$ and $\beta = \pm 1$,

$$f(1) = f(0) + f'(0) + \frac{f''(0)}{2} + \frac{f'''(s)}{6}$$
 (I)

$$f(-1) = f(0) - f'(0) + \frac{f''(0)}{2} - \frac{f'''(t)}{6}$$
 (II)

for some $s \in (0, 1)$ and $t \in (-1, 0)$.

(2) (I) subtracts (II) implies that

$$f(1) - f(-1) = 2f'(0) + \frac{f'''(s)}{6} + \frac{f'''(t)}{6}.$$

By assumption, f(-1) = 0, f(1) = 1 and f'(0) = 0. Hence

$$f^{(3)}(s) + f^{(3)}(t) = 6$$

for some $s \in (0,1)$ and $t \in (-1,0)$. So either $f^{(3)}(s) \ge 3$ or $f^{(3)}(t) \ge 3$ for some $s, t \in (-1,1)$.

Exercise 5.18. Suppose f is a real function on [a,b], n is a positive integer, and $f^{(n-1)}$ exists for every $t \in [a,b]$. Let α , β , and P be as in Taylor's theorem (Theorem 5.15). Define

$$Q(t) = \frac{f(t) - f(\beta)}{t - \beta}$$

for $t \in [a, b]$, $t \neq \beta$, differentiate

$$f(t) - f(\beta) = (t - \beta)Q(t)$$

n-1 times at $t=\alpha$, and derive the following version of Taylor's theorem:

$$f(\beta) = P(\beta) + \frac{Q^{(n-1)}(\alpha)}{(n-1)!} (\beta - \alpha)^n.$$

Proof.

(1) Show that

$$f^{(k)}(t) = kQ^{(k-1)}(t) + (t - \beta)Q^{(k)}(t)$$

for k = 1, 2, ..., n. Induction on k.

(a) If k = 1, then

$$f'(t) = Q(t) + (t - \beta)Q'(t)$$

(Theorem 5.3(b)).

(b) Assume the induction hypothesis that for the single case k=m-1 holds. Apply Theorem 5.3(b) again to get

$$\begin{split} f^{(m)}(t) &= (f^{(m-1)}(t))' \\ &= ((m-1)Q^{(m-2)}(t) + (t-\beta)Q^{(m-1)}(t))' \\ &= (m-1)Q^{(m-1)}(t) + Q^{(m-1)}(t) + (t-\beta)Q^{(m)}(t) \\ &= mQ^{(m-1)}(t) + (t-\beta)Q^{(m)}(t). \end{split}$$

- (c) Since both the base case in (a) and the inductive step in (b) have been proved as true, by mathematical induction the result holds.
- (2) Show that

$$f(\beta) = P(\beta) + \frac{Q^{(n-1)}(\alpha)}{(n-1)!} (\beta - \alpha)^n$$

where

$$P(t) = \sum_{k=0}^{n-1} \frac{f^{(k)}(\alpha)}{k!} (t - \alpha)^k.$$

Induction on n.

(a) If n = 1, then by the definition of Q(t)

$$f(\beta) = f(\alpha) + Q(\alpha)(\beta - \alpha).$$

(b) Assume the induction hypothesis that for the single case n = m - 1 holds. By (1), we have

$$Q^{(m-2)}(\alpha) = \frac{1}{m-1} (f^{(m-1)}(\alpha) + Q^{(m-1)}(\alpha)(\beta - \alpha)).$$

Hence

$$f(\beta) = \sum_{k=0}^{m-2} \frac{f^{(k)}(\alpha)}{k!} (\beta - \alpha)^k + \frac{Q^{(m-2)}(\alpha)}{(m-2)!} (\beta - \alpha)^{m-1}$$

$$= \sum_{k=0}^{m-2} \frac{f^{(k)}(\alpha)}{k!} (\beta - \alpha)^k$$

$$+ \frac{f^{(m-1)}(\alpha)}{(m-1)!} (\beta - \alpha)^{m-1} + \frac{Q^{(m-1)}(\alpha)(\beta - \alpha)}{(m-1)!} (\beta - \alpha)^{m-1}$$

$$= \sum_{k=0}^{m-1} \frac{f^{(k)}(\alpha)}{k!} (\beta - \alpha)^k + \frac{Q^{(m-1)}(\alpha)}{(m-1)!} (\beta - \alpha)^m.$$

(c) Since both the base case in (a) and the inductive step in (b) have been proved as true, by mathematical induction the result holds.

Note. It is also true for vector-valued functions: Suppose \mathbf{f} is a function of [a,b] into \mathbb{R}^m , n is a positive integer, $\mathbf{f}^{(n-1)}$ is continuous on [a,b], $\mathbf{f}^{(n)}(t)$ exists for every $t \in (a,b)$. Let α , β be distinct points of [a,b], and define

$$\mathbf{P}(t) = \sum_{k=0}^{n-1} \frac{\mathbf{f}^{(k)}(\alpha)}{k!} (t - \alpha)^k$$

and

$$\mathbf{Q}(t) = \frac{\mathbf{f}(t) - \mathbf{f}(\beta)}{t - \beta}.$$

Then

$$\mathbf{f}(\beta) = \mathbf{P}(\beta) + \frac{\mathbf{Q}^{(n-1)}(\alpha)}{(n-1)!} (\beta - \alpha)^n.$$

Exercise 5.19. Suppose f is defined in (-1,1) and f'(0) exists. Suppose $-1 < \alpha_n < \beta_n < 1$, $\alpha_n \to 0$, and $\beta_n \to 0$ as $n \to \infty$. Define the difference quotients

$$D_n = \frac{f(\beta_n) - f(\alpha_n)}{\beta_n - \alpha_n}$$

Prove the following statements:

- (a) If $\alpha_n < 0 < \beta_n$, then $\lim D_n = f'(0)$.
- (b) If $0 < \alpha_n < \beta_n$ and $\left\{ \frac{\beta_n}{\beta_n \alpha_n} \right\}$ is bounded, then $\lim D_n = f'(0)$.
- (c) If f' is continuous in (-1,1), then $\lim D_n = f'(0)$.

Give an example in which f is differentiable in (-1,1) (but f' is not continuous at 0) and in which α_n , β_n tend to 0 in such a way that $\lim D_n$ exists but is different from f'(0).

Proof of (a).

(1) Write

$$D_n = \frac{f(\beta_n) - f(0)}{\beta_n - 0} \cdot \frac{\beta_n}{\beta_n - \alpha_n} - \frac{f(\alpha_n) - f(0)}{\alpha_n - 0} \cdot \frac{\alpha_n}{\beta_n - \alpha_n}.$$

It is well-defined since $\alpha_n \neq 0$ and $\beta_n \neq 0$.

(2) Given any $\varepsilon > 0$. Since f'(0) exists, there exists a common integer N such that

$$\left| \frac{f(\alpha_n) - f(0)}{\alpha_n - 0} - f'(0) \right| < \varepsilon \text{ and } \left| \frac{f(\beta_n) - f(0)}{\beta_n - 0} - f'(0) \right| < \varepsilon$$

whenever $n \geq N$.

(3) Thus

$$|D_{n} - f'(0)|$$

$$\leq \frac{\beta_{n}}{\beta_{n} - \alpha_{n}} \cdot \left| \frac{f(\beta_{n}) - f(0)}{\beta_{n} - 0} - f'(0) \right| + \frac{-\alpha_{n}}{\beta_{n} - \alpha_{n}} \cdot \left| \frac{f(\alpha_{n}) - f(0)}{\alpha_{n} - 0} - f'(0) \right|$$

$$< \frac{\beta_{n}}{\beta_{n} - \alpha_{n}} \varepsilon + \frac{-\alpha_{n}}{\beta_{n} - \alpha_{n}} \varepsilon$$

$$= \varepsilon.$$

whenever $n \geq N$. Therefore, $\lim D_n = f'(0)$.

Proof of (b).

(1) Similar to (1) in the proof of (a). Write

$$D_n = \frac{f(\beta_n) - f(0)}{\beta_n - 0} \cdot \frac{\beta_n}{\beta_n - \alpha_n} - \frac{f(\alpha_n) - f(0)}{\alpha_n - 0} \cdot \frac{\alpha_n}{\beta_n - \alpha_n}.$$

It is well-defined since $\alpha_n \neq 0$ and $\beta_n \neq 0$.

(2) Write

$$\left| \frac{\beta_n}{\beta_n - \alpha_n} \right| \le M$$

for some real $M \ge 0$. Hence $\left\{\frac{\alpha_n}{\beta_n - \alpha_n}\right\}$ is bounded too, say

$$\left|\frac{\alpha_n}{\beta_n - \alpha_n}\right| = \left|\frac{\beta_n}{\beta_n - \alpha_n} - 1\right| \le M + 1.$$

(3) Given any $\varepsilon > 0$. Since f'(0) exists, there exists a common integer N such that

$$\left| \frac{f(\alpha_n) - f(0)}{\alpha_n - 0} - f'(0) \right| < \frac{\varepsilon}{64(M+1)},$$
$$\left| \frac{f(\beta_n) - f(0)}{\beta_n - 0} - f'(0) \right| < \frac{\varepsilon}{89(M+1)}$$

whenever $n \geq N$.

(4) Thus

$$|D_{n} - f'(0)|$$

$$\leq \left| \frac{\beta_{n}}{\beta_{n} - \alpha_{n}} \right| \cdot \left| \frac{f(\beta_{n}) - f(0)}{\beta_{n} - 0} - f'(0) \right|$$

$$+ \left| \frac{-\alpha_{n}}{\beta_{n} - \alpha_{n}} \right| \cdot \left| \frac{f(\alpha_{n}) - f(0)}{\alpha_{n} - 0} - f'(0) \right|$$

$$< \frac{M}{89(M+1)} \varepsilon + \frac{M+1}{64(M+1)} \varepsilon$$

$$< \frac{\varepsilon}{89} + \frac{\varepsilon}{64}$$

$$< \varepsilon$$

whenever $n \geq N$. Therefore, $\lim D_n = f'(0)$.

Proof of (c). By the mean value theorem (Theorem 5.10), there is point $\xi_n \in (\alpha_n, \beta_n)$ at which

$$f(\beta_n) - f(\alpha_n) = (\beta_n - \alpha_n)f'(\xi_n)$$

or

$$f'(\xi_n) = \frac{f(\beta_n) - f(\alpha_n)}{\beta_n - \alpha_n} = D_n.$$

Since $\xi_n \in (\alpha_n, \beta_n)$ and $\lim \alpha_n = \lim \beta_n = 0$, $\lim \xi_n = 0$. Since f' is continuous at x = 0,

$$\lim D_n = \lim f'(\xi_n) = f'(\lim \xi_n) = f'(0).$$

Note.

- (1) Give an example in which f is differentiable in (-1,1) (but f' is not continuous at 0) and in which α_n , β_n tend to 0 in such a way that $\lim D_n$ exists but is different from f'(0).
- (2) Let f be defined by

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} & (x \neq 0), \\ 0 & (x = 0) \end{cases}$$

as in Examples 5.6(b). So

$$f'(x) = \begin{cases} 2x \sin \frac{1}{x} - \cos \frac{1}{x} & (x \neq 0), \\ 0 & (x = 0). \end{cases}$$

(3) Take $\alpha_n = (2n\pi)^{-1} \neq 0$ and $\beta_n = (\frac{\pi}{2} + 2n\pi)^{-1} \neq 0$ for $n = 1, 2, 3, \dots$ Hence $\lim \alpha_n = \lim \beta_n = 0$, and

$$\lim D_n = \lim \frac{\left(\frac{\pi}{2} + 2n\pi\right)^{-2}}{\left(\frac{\pi}{2} + 2n\pi\right)^{-1} - (2n\pi)^{-1}}$$

$$= \lim \frac{2n\pi}{\left(2n\pi\right)\left(\frac{\pi}{2} + 2n\pi\right) - \left(\frac{\pi}{2} + 2n\pi\right)^2}$$

$$= \lim \frac{2n\pi}{-\frac{\pi}{2}\left(\frac{\pi}{2} + 2n\pi\right)}$$

$$= -\frac{2}{\pi} \neq f'(0).$$

Exercise 5.20. Formulate and prove an inequality which follows form Taylor's theorem and which remains valid for vector-valued function.

Proof.

(1) Suppose \mathbf{f} is a function of [a,b] into \mathbb{R}^m , n is a positive integer, $\mathbf{f}^{(n-1)}$ is continuous on [a,b], $\mathbf{f}^{(n)}(t)$ exists for every $t \in (a,b)$. Let α , β be distinct points of [a,b], and define

$$\mathbf{P}(t) = \sum_{k=0}^{n-1} \frac{\mathbf{f}^{(k)}(\alpha)}{k!} (t - \alpha)^k.$$

Then there exists a point x between α and β such that

$$|\mathbf{f}(\beta) - \mathbf{P}(\beta)| \le (\beta - \alpha)^n \left| \frac{\mathbf{f}^{(n)}(x)}{n!} \right|.$$

For n = 1, this is just Theorem 5.19.

(2) Similar to the proof of Theorem 5.19. Put

$$\mathbf{z} = \mathbf{f}(\beta) - \mathbf{P}(\beta).$$

Define

$$\varphi(t) = \mathbf{z} \cdot \mathbf{f}(t) \qquad (\alpha \le t \le \beta).$$

Then $\varphi(t)$ is a function of [a,b] into \mathbb{R}^1 , and

$$\varphi^{(k)}(t) = \mathbf{z} \cdot \mathbf{f}^{(k)}(t)$$

where $0 \le k \le n$. Also, $\varphi^{(n-1)}$ is continuous on $[\alpha, \beta]$, and $\varphi^{(n)}(t)$ exists for every $t \in (\alpha, \beta)$.

(3) By Taylor's theorem (Theorem 5.15), there exists $x \in (\alpha, \beta)$ such that

$$\varphi(\beta) = Q(\beta) + \frac{\varphi^{(n)}(x)}{n!} (\beta - \alpha)^n$$

where

$$Q(t) = \sum_{k=0}^{n-1} \frac{\varphi^{(k)}(\alpha)}{k!} (t - \alpha)^k.$$

By (2), we have $Q(t) = \mathbf{z} \cdot \mathbf{P}(t)$ and thus

$$\mathbf{z} \cdot (\mathbf{f}(\beta) - \mathbf{P}(\beta)) = \mathbf{z} \cdot \frac{\mathbf{f}^{(n)}(x)}{n!} (\beta - \alpha)^n.$$

Note that $\mathbf{z} = \mathbf{f}(\beta) - \mathbf{P}(\beta)$ and Schwarz inequality (Theorem 1.37(d)). Hence

$$|\mathbf{f}(\beta) - \mathbf{P}(\beta)|^2 = \left| (\mathbf{f}(\beta) - \mathbf{P}(\beta)) \cdot \frac{\mathbf{f}^{(n)}(x)}{n!} (\beta - \alpha)^n \right|$$

$$\leq |\mathbf{f}(\beta) - \mathbf{P}(\beta)| \left| \frac{\mathbf{f}^{(n)}(x)}{n!} \right| (\beta - \alpha)^n$$

or

$$|\mathbf{f}(\beta) - \mathbf{P}(\beta)| \le \left| \frac{\mathbf{f}^{(n)}(x)}{n!} \right| (\beta - \alpha)^n$$

(whether $\mathbf{f}(\beta) - \mathbf{P}(\beta)$ is zero nor not).

Exercise 5.21. Let E be a closed subset of \mathbb{R}^1 . We saw in Exercise 4.22, that there is a real continuous function f on \mathbb{R}^1 whose zero set is E. Is it possible, for each closed set E, to find such an f which is differentiable on \mathbb{R}^1 , or one which is n times differentiable, or even one which has derivatives of all orders on \mathbb{R}^1 ?

It is possible by leveraging Exercise 8.1.

Proof.

- (1) Every open set in \mathbb{R}^1 is the union of an at most countable collection of disjoint segments (Exercise 2.29).
- (2) We need to construct an infinitely differentiable real function f on \mathbb{R}^1 such that the zero set Z(f) is E. By (1), write \widetilde{E} as the union of an at most countable collection of disjoint segments, say

$$\widetilde{E} = \bigcup_{(a_i, b_i) \in \mathscr{C}} (a_i, b_i)$$

where \mathscr{C} is at most countable and all (a_i, b_i) segments are disjoint.

(3) For each disjoint segment (a_i, b_i) of

$$\widetilde{E} = \bigcup_{(a_i, b_i) \in \mathscr{C}} (a_i, b_i),$$

define f(x) on \mathbb{R}^1 by

$$f(x) = \begin{cases} 1 & (x \in (-\infty, \infty)), \\ \exp\left(-\frac{1}{(x-a_i)^2}\right) & (x \in (a_i, \infty), a_i \neq -\infty), \\ \exp\left(-\frac{1}{(x-b_i)^2}\right) & (x \in (-\infty, b_i), b_i \neq \infty), \\ \exp\left(-\frac{1}{(x-a_i)^2(x-b_i)^2}\right) & (x \in (a_i, b_i), a_i \neq -\infty, b_i \neq \infty), \\ 0 & (x \in E). \end{cases}$$

By construction, f(x) = 0 if and only if $x \in E$ (Theorem 8.6(c)). By the same argument in the proof of Exercise 8.1, f(x) is infinitely differentiable on \mathbb{R}^1 .

Exercise 5.22. Suppose f is a real function on $(-\infty, +\infty)$. Call x a **fixed point** of f if f(x) = x.

- (a) If f is differentiable and $f'(t) \neq 1$ for every real t, prove that f has at most one fixed point.
- (b) Show that the function f defined by

$$f(t) = t + (1 + e^t)^{-1}$$

has no fixed point, although 0 < f'(t) < 1 for all real t.

(c) However, if there is a constant A < 1 such that $|f'(t)| \le A$ for all real t, prove that a fixed point x of f exists, and that $x = \lim x_n$, where x_1 is an arbitrary real number and

$$x_{n+1} = f(x_n)$$

for n = 1, 2, 3, ...

(d) Show that the process describe in (c) can be visualized by the zig-zag path

$$(x_1, x_2) \to (x_2, x_2) \to (x_2, x_3) \to (x_3, x_3) \to (x_3, x_4) \to \dots$$

Exercise 5.23. The function f defined by

$$f(x) = \frac{x^3 + 1}{3}$$

has three fixed points, say α , β , γ , where

$$2 < \alpha < 1$$
, $0 < \beta < 1$, $1 < \gamma < 2$.

For arbitrarily chosen x_1 , define $\{x_n\}$ by setting $x_{n+1} = f(x_n)$.

- (a) If $x_1 < \alpha$, prove that $x_n \to -\infty$ as $n \to \infty$.
- (b) If $\alpha < x_1 < \gamma$, prove that $x_n \to \beta$ as $n \to \infty$.
- (c) If $\gamma < x_1$, prove that $x_n \to +\infty$ as $n \to \infty$.

Thus β can be located by this method, but α and γ cannot.

Exercise 5.24. The process described in part (c) of Exercise 5.22 can of course also be applied to functions that map $(0,\infty)$ to $(0,\infty)$. Fix some $\alpha > 1$, and put

$$f(x) = \frac{1}{2} \left(x + \frac{\alpha}{x} \right), \qquad g(x) = \frac{\alpha + x}{1 + x}.$$

Both f and g have $\sqrt{\alpha}$ as their fixed point in $(0,\infty)$. Try to explain, on the basis of properties of f and g, why the convergence in Exercise 3.16, is so much more rapid than it is in Exercise 3.17. (Compare f' and g', draw the zig-zags suggested in Exercise 5.22.)

Exercise 5.25. Suppose f is twice differentiable on [a,b], f(a) < 0, f(b) > 0, $f'(x) \ge \delta > 0$, and $0 \le f''(x) \le M$ for all $x \in [a,b]$. Let ξ be the unique point in (a,b) at which $f(\xi) = 0$. Complete the details in the following outline of **Newton's method** for computing ξ .

(a) Choose $x_1 \in (\xi, b)$, and define $\{x_n\}$ by

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$$

Interpret this geometrically, in terms of a tangent to the graph of f.

(b) Prove that $x_{n+1} < x_n$ and that

$$\lim_{n \to \infty} x_n = \xi.$$

(c) Use Taylor's theorem to show that

$$x_{n+1} - \xi = \frac{f''(t_n)}{2f'(x_n)}(x_n - \xi)^2$$

for some $t_n \in (\xi, x_n)$.

(d) (Quadratic convergence) If $A = \frac{M}{2\delta}$, deduce that

$$0 \le x_{n+1} - \xi \le \frac{1}{A} [A(x_1 - \xi)]^{2^n}.$$

(Compare with Exercise 3.16 and 3.18.)

(e) Show that Newton's method amounts to finding a fixed point of the function g defined by

$$g(x) = x - \frac{f(x)}{f'(x)}.$$

How does g'(x) behave for x near ξ ?

(f) Put $f(x) = x^{\frac{1}{3}}$ on $(-\infty, +\infty)$ and try Newton's method. What happens?

Proof of (a) (Wikipedia). The equation of the tangent line to the curve y = f(x) at $x = x_n$ is

$$y = f'(x_n)(x - x_n) + f(x_n).$$

The x-intercept of this line (the value of x which makes y = 0) is taken as the next approximation, x_{n+1} , to the root, so that the equation of the tangent line is satisfied when $(x, y) = (x_{n+1}, 0)$:

$$0 = f'(x_n)(x - x_n) + f(x_n).$$

Solving for x_{n+1} gives

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$$

Proof of (b).

- (1) Show that $x_n \geq \xi$ for all n. Induction on n.
 - (a) n = 1 is clearly true: $x_1 > \xi$ by assumption.
 - (b) Assume the induction hypothesis that for the single case n=k holds. By the mean value theorem (Theorem 5.10), there is a point $\xi_k \in (\xi, x_k)$

$$f(x_k) - f(\xi) = f'(\xi_k)(x_k - \xi),$$

or

$$f(x_k) = f'(\xi_k)(x_k - \xi)$$

(since $f(\xi) = 0$). Since $f'' \ge 0$, f' is monotonically increasing (Theorem 5.11(a)). Hence $f'(\xi_k) \le f'(x_k)$ and thus

$$f(x_k) = f'(\xi_k)(x_k - \xi) \le f'(x_k)(x_k - \xi).$$

Since $f'(x_k) > 0$ by assumption,

$$\xi \le x_k - \frac{f(x_k)}{f'(x_k)} = x_{k+1}.$$

- (c) Since both the base case in (a) and the inductive step in (b) have been proved as true, by mathematical induction $x_n \geq \xi$ for all n.
- (2) Show that $x_{n+1} < x_n$ for all n.
 - (a) Since f' > 0, $f'(x_n) > 0$ for all n.
 - (b) Since f' > 0, f is strictly increasing (Theorem 5.10). Hence $f(x_n) > f(\xi) = 0$ for all n (by (1)).
 - (c) By (a)(b), $\frac{f(x_n)}{f'(x_n)} > 0$ or

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} < x_n.$$

(3) By Theorem 3.14, $\{x_n\}$ converges to some real number $\zeta \geq \xi$. Note that f and f' are continuous by the existence of f'' (Theorem 5.2), we have

$$\lim_{n \to \infty} x_{n+1} = \lim_{n \to \infty} x_n - \frac{f(\lim_{n \to \infty} x_n)}{f'(\lim_{n \to \infty} x_n)}$$

provided $f' \neq 0$ (Theorem 4.9 and Theorem 4.4). Hence

$$\zeta = \zeta - \frac{f(\zeta)}{f'(\zeta)}$$

or $f(\zeta) = 0$. By the uniqueness of ξ , $\zeta = \xi$ or $\lim x_n = \xi$ as desired.

Proof of (c). By Taylor's theorem (Theorem 5.15),

$$f(\xi) = f(x_n) + f'(x_n)(\xi - x_n) + \frac{f''(t_n)}{2}(\xi - x_n)^2$$

for some $t_n \in (\xi, x_n)$. Note that $f(\xi) = 0$, $f'(x_n) \neq 0$ and $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$, we have the desired result. \square

Proof of (d). Clearly, $0 \le x_{n+1} - \xi$ for all n (by (b)). Besides, by (c)

$$x_{n+1} - \xi = \frac{f''(t_n)}{2f'(x_n)}(x_n - \xi)^2$$

Note that $f'' \leq M$ and $f' \geq \delta > 0$ by assumption, and thus

$$x_{n+1} - \xi \le \frac{M}{2\delta} (x_n - \xi)^2 = A(x_n - \xi)^2.$$

By induction,

$$x_{n+1} - \xi \le \frac{1}{A} (A(x_1 - \xi))^{2^n}.$$

Note. Compare with Exercise 3.16 and Exercise 3.18. Might assume that p > 1.

(1) Fix a positive number α . Let $f(x) = x^p - \alpha$ on E = (a, b) where $a = \frac{1}{2}\alpha^{\frac{1}{p}}$ and

$$b = \begin{cases} 2\alpha^{\frac{1}{p}} & (p=2), \\ \left(\frac{2(p-1)}{p}\right)^{\frac{1}{p-2}} \alpha^{\frac{1}{p}} & (p>2). \end{cases}$$

E = (a, b) is well-defined since a < b. Besides, $\xi = \alpha^{\frac{1}{p}} \in E = (a, b)$.

(2) By construction,

$$f(a) < 0 \text{ and } f(b) > 0.$$

By
$$f'(x) = px^{p-1}$$
 and $f''(x) = p(p-1)x^{p-2}$,

$$f'(x) \ge pa^{p-1} > 0,$$

 $0 \le f''(x) \le p(p-1)b^{p-2}.$

on E. Write

$$\delta = pa^{p-1} = \frac{p}{2^{p-1}} \alpha^{\frac{p-1}{p}},$$

$$M = p(p-1)b^{p-2} = 2(p-1)^2 \alpha^{\frac{p-2}{p}}.$$

(3) Hence the Newton's method works for $f(x) = x^p - \alpha$. That is, as we define $\{x_n\}$ by

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = \frac{p-1}{p}x_n + \frac{\alpha}{p}x_n^{-p+1},$$

we have $\lim x_n = \xi = \alpha^{\frac{1}{p}}$. And

$$0 \le x_{n+1} - \xi \le \frac{1}{A} (A(x_1 - \xi))^{2^n}.$$

Here

$$A = \frac{M}{2\delta} = \frac{2^{p-1}(p-1)^2}{n\alpha^{\frac{1}{p}}}.$$

(4) Note that

$$\beta = \frac{p\alpha^{\frac{1}{p}}}{(p-1)^2} \neq \frac{p\alpha^{\frac{1}{p}}}{2^{p-1}(p-1)^2} = \frac{1}{A}.$$

where β is defined in the proof of Exercise 3.18. Note that $f'(x_n) \geq f'(\xi)$ (since f' is monotonically increasing and all $x_n \geq \xi$), and thus A can be chosen by a better estimation:

$$A = \frac{M}{2f'(\xi)} = \frac{(p-1)^2}{p\alpha^{\frac{1}{p}}} = \frac{1}{\beta}.$$

Now it is exactly the same as Exercise 3.16 and Exercise 3.18.

Proof of (e).

- (1) Define $g(x) = x \frac{f(x)}{f'(x)}$ on [a, b]. $g(\xi) = \xi$ if and only if $f(\xi) = 0$.
- (2) By the construction of g, g is differentiable and

$$g'(x) = 1 - \frac{f'(x)^2 - f(x)f''(x)}{f'(x)^2} = \frac{f(x)f''(x)}{f'(x)^2}.$$

(3) Hence

$$|g'(x)| \le \left| \frac{f(x)f''(x)}{f'(x)^2} \right| = \frac{|f(x)||f''(x)|}{|f'(x)|^2} \le \frac{M}{\delta^2} |f(x)|.$$

As $x \to \xi$, $|f(x)| \to 0$. Therefore, $|g'(x)| \to 0$ or $g'(x) \to 0$ as $x \to \xi$.

Proof of (f).

- (1) It is clearly that f(x) = 0 if and only if x = 0. Write $\xi = 0$.
- (2) Note that

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} = -2x_n,$$

or

$$x_n = (-2)^{n-1}x_1$$

for any $x_1 \in (\xi, \infty)$ where $n = 1, 2, 3, \ldots$ Hence, the sequence $\{x_n\}$ does not converge for any choice of $x_1 \in (\xi, \infty)$. In this case we cannot find ξ satisfying $f(\xi) = 0$ by Newton's method.

(3) In fact,

$$f'(x) = \frac{1}{3}x^{-\frac{2}{3}} \to 0 \text{ as } x \to \pm \infty.$$

Hence such $\delta > 0$ satisfying $f'(x) \geq \delta > 0$ does not exist.

Exercise 5.26. Suppose f is differentiable on [a,b], f(a)=0, and there is a real number A such that $|f'(x)| \leq A|f(x)|$ on [a,b]. Prove that f(x)=0 for all $x \in [a,b]$. (Hint: Fix $x_0 \in [a,b]$, let

$$M_0 = \sup |f(x)|, \qquad M_1 = \sup |f'(x)|$$

for $a \le x \le x_0$. For any such x,

$$|f(x)| \le M_1(x_0 - a) \le A(x_0 - a)M_0.$$

Hence $M_0 = 0$ if $A(x_0 - a) < 1$. That is, f = 0 on $[a, x_0]$. Proceed.)

Proof (Hint).

- (1) If A = 0, then f'(x) = 0 or f(x) is constant on [a, b] (Theorem 5.11(b)). Since f(a) = 0, f(x) = 0 on [a, b].
- (2) Suppose that A > 0. Fix $x_0 \in [a, b]$, let

$$M_0 = \sup |f(x)|, \qquad M_1 = \sup |f'(x)|$$

for $a \le x \le x_0$. Since $|f'(x)| \le A|f(x)|$ on [a, b],

$$|f'(x)| \le A|f(x)| \le AM_0.$$

Since AM_0 is an upper bound for |f'(x)|,

$$M_1 \leq AM_0$$
.

(3) Given any $x \in [a, x_0]$. Since f is differentiable on $[a, x_0] \subseteq [a, b]$, by the mean value theorem (Theorem 5.10), there is $\xi \in (a, x)$ such that

$$f(x) - f(a) = f'(\xi)(x - a).$$

Note that f(a) = 0 by assumption. So that

$$|f(x)| = |f'(\xi)|(x-a)$$

$$\leq M_1(x-a) \qquad \text{(Definition of } M_1\text{)}$$

$$\leq AM_0(x-a) \qquad \text{((2))}$$

$$\leq AM_0(x_0-a). \qquad (x \in [a,x_0])$$

Since $AM_0(x_0 - a)$ is an upper bound for |f(x)|,

$$M_0 \le AM_0(x_0 - a).$$

Take

$$x_0 = \min\left\{\frac{1}{2A} + a, b\right\}$$

so that $M_0 \le AM_0(x_0 - a) \le \frac{M_0}{2}$. $M_0 = 0$ or f(x) = 0 on $[a, x_0]$.

(4) Take a partition

$$P = \{a = x_{-1}, x_0, \dots, x_n = b\}$$

of [a, b] such that each subinterval $[x_{i-1}, x_i]$ satisfying $\Delta x_i = x_i - x_{i-1} < \frac{1}{2A}$. By (3), f(x) = 0 on $[x_{-1}, x_0]$. Apply the same argument in (3), f(x) = 0 on $[x_0, x_1]$. Continue this process, f(x) = 0 on each subinterval and thus on the whole interval [a, b].

Note. It holds for vector-valued functions too:

Suppose **f** is a vector-valued differentiable function on [a,b], f(a) = 0, and there is a real number A such that $|\mathbf{f}'(x)| \leq A|\mathbf{f}(x)|$ on [a,b]. Prove that $\mathbf{f}(x) = 0$ for all $x \in [a,b]$.

The proof is similar except using Theorem 5.19 $(|\mathbf{f}(b) - \mathbf{f}(a)| \le (b-a)|\mathbf{f}'(x)|)$ in addition.

Exercise 5.27. Let ϕ be a real function defined on a rectangle R in the plane, given by $a \le x \le b$, $\alpha \le y \le \beta$. A **solution** of the initial-value problem

$$y' = \phi(x, y), \quad y(a) = c \quad (\alpha \le c \le \beta)$$

is, by definition, a differentiable function f on [a,b] such that $f(a)=c,\ \alpha\leq f(x)\leq \beta,\ and$

$$f'(x) = \phi(x, f(x))$$
 $(a \le x \le b)$

Prove that such a problem has at most one solution if there is a constant A such that

$$|\phi(x, y_2) - \phi(x, y_1)| \le A|y_2 - y_1|$$

whenever $(x, y_1) \in R$ and $(x, y_2) \in R$. (Hint: Apply Exercise 26 to the difference of two solutions.) Note that this uniqueness theorem does not hold for the initial-value problem

$$y' = y^{\frac{1}{2}}, \qquad y(0) = 0,$$

which has two solutions: f(x) = 0 and $f(x) = \frac{x^2}{4}$. Find all other solutions.

Proof (Hint).

(1) Suppose f_1 and f_2 are two solutions of that problem. Define $f = f_1 - f_2$. f is differentiable on [a, b], $f(a) = f_1(a) - f_2(a) = c - c = 0$. And

$$|f'(x)| = |f'_1(x) - f'_2(x)|$$

= $|\phi(x, f_1(x)) - \phi(x, f_2(x))|$
 $\leq A|f_1(x) - f_2(x)|$

on [a, b]. By Exercise 5.26, f(x) = 0 on [a, b], or $f_1(x) = f_2(x)$ on [a, b].

(2) The initial-value problem

$$y' = y^{\frac{1}{2}}, \qquad y(0) = 0,$$

which has two solutions: f(x) = 0 and $f(x) = \frac{x^2}{4}$. Find all other solutions.

Note. It does not exist a real A such that $|\phi(x,y_2) - \phi(x,y_1)| \le A|y_2 - y_1|$ in this initial-value problem.

- (a) Clearly, f(x) = 0 and $f(x) = \frac{x^2}{4}$ are two solutions for the initial-value problem.
- (b) Suppose $f(x) \neq 0$ on $[0, \infty)$. Since $f'(x) = f(x)^{\frac{1}{2}}$, $f(x) \geq 0$. Since f(x) is continuous (Theorem 5.2), the set

$$E = \{x \in [0, \infty) : f(x) > 0\}$$

is open in \mathbb{R}^1 (Theorem 4.8). By Exercise 2.29 we write E as the union of an at most countable collection of disjoint segments, say

$$E = \bigcup_{(a_i, b_i) \in \mathscr{C}} (a_i, b_i)$$

where \mathscr{C} is at most countable and all (a_i, b_i) segments are disjoint. Note that E (or \mathscr{C}) is nonempty.

(c) For any segment (a_i, b_i) , define $g(x) = f(x)^{\frac{1}{2}}$ on (a_i, b_i) . (Clearly, $g(a_i) = f(a_i) = 0$ by the definition of E.) Thus

$$g'(x) = \frac{1}{2}f(x)^{-\frac{1}{2}}f'(x) = \frac{1}{2}.$$

Hence

$$g(x) = \frac{1}{2}x + c$$

for some constant $c \in \mathbb{R}^1$. So

$$f(x) = g(x)^2 = \left(\frac{1}{2}x + c\right)^2.$$

 $f(a_i) = 0$ implies that $c = -\frac{a_i}{2}$. Hence

$$f(x) = \frac{1}{4}(x - a_i)^2$$

on (a_i, b_i) .

(d) By (c), if $b_i < 0$ is defined as a real number, then $f(b_i) = 0$ by definition of E. Note that

$$\lim_{x \to b_i -} f(x) = \frac{1}{4} (b_i - a_i)^2 > 0,$$

which is absurd. Hence $b_i = \infty$ and thus E is of the form

$$E = (a, \infty) \qquad (a \ge 0).$$

Therefore,

$$f(x) = \begin{cases} 0 & (0 \le x \le a), \\ \frac{1}{4}(x-a)^2 & (x > a \ge 0). \end{cases}$$

Exercise 5.28. Formulate and prove an analogous uniqueness theorem for systems of differential equations of the form

$$y'_{j} = \phi_{j}(x, y_{1}, \dots, y_{k}), \quad y_{j}(a) = c_{j} \quad (j = 1, \dots, k)$$

Note that this can be rewritten in the form

$$\mathbf{y}' = \boldsymbol{\phi}(x, \mathbf{y}), \qquad \mathbf{y}(a) = \mathbf{c}$$

where $\mathbf{y} = (y_1, \dots, y_k)$ ranges over a k-cell, $\boldsymbol{\phi}$ is the mapping of a (k+1)-cell into the Euclidean k-space whose components are the function ϕ_1, \dots, ϕ_k , and \mathbf{c} is the vector (c_1, \dots, c_k) . Use Exercise 5.26, for vector-valued functions.

Proof.

(1) A solution of the initial-value problem

$$\mathbf{y}' = \boldsymbol{\phi}(x, \mathbf{y}), \quad \mathbf{y}(a) = \mathbf{c}$$

is, by definition, a differentiable function \mathbf{f} on [a,b] such that $\mathbf{f}(a) = \mathbf{c}$, and

$$\mathbf{f}'(x) = \phi(x, \mathbf{f}(x)) \qquad (a < x < b).$$

Then this problem has at most one solution if there is a constant A such that

$$|\phi(x, \mathbf{y}_2) - \phi(x, \mathbf{y}_1)| \le A|\mathbf{y}_2 - \mathbf{y}_1|$$

whenever $(x, y_1) \in R$ and $(x, y_2) \in R$ where R is a (k+1)-cell defined by

$$R = [a, b] \times [\alpha_1, \beta_1] \times \cdots \times [\alpha_k, \beta_k].$$

(2) Similar to Exercise 5.27, Suppose \mathbf{f}_1 and \mathbf{f}_2 are two solutions of that problem. Define $\mathbf{f} = \mathbf{f}_1 - \mathbf{f}_2$. \mathbf{f} is differentiable on [a, b], $\mathbf{f}(a) = \mathbf{f}_1(a) - \mathbf{f}_2(a) = \mathbf{c} - \mathbf{c} = 0$. And

$$|\mathbf{f}'(x)| = |\mathbf{f}'_1(x) - \mathbf{f}'_2(x)|$$

= $|\boldsymbol{\phi}(x, \mathbf{f}_1(x)) - \boldsymbol{\phi}(x, \mathbf{f}_2(x))|$
 $\leq A|\mathbf{f}_1(x) - \mathbf{f}_2(x)|$

on [a, b]. By Note in Exercise 5.26, $\mathbf{f}(x) = 0$ on [a, b], or $\mathbf{f}_1(x) = \mathbf{f}_2(x)$ on [a, b].

Exercise 5.29. Specialize Exercise 5.28 by considering the system

$$y'_{j} = y_{j+1}$$
 $(j = 1, ..., k-1),$
 $y'_{k} = f(x) - \sum_{j=1}^{k} g_{j}(x)y_{j}$

where f, g_1, \ldots, g_k are continuous real functions on [a, b], and derive a uniqueness theorem for solutions of the equation

$$y^{(k)} + g_k(x)y^{(k-1)} + \dots + g_2(x)y' + g_1(x)y = f(x),$$

 $subject\ to\ initial\ conditions$

$$y(a) = c_1,$$
 $y'(a) = c_1,$ $\dots,$ $y^{(k-1)}(a) = c_k.$

Proof.

(1) Write

$$\mathbf{y} = (y_1, \dots, y_k)$$

$$= (y, y', y'', \dots, y^{(k-1)}),$$

$$\phi(x, \mathbf{y}) = \left(y_2, y_3, \dots, y_{k-1}, f(x) - \sum_{j=1}^k g_j(x)y_j\right)$$

$$= \left(y', y'', \dots, y^{(k-1)}, f(x) - \sum_{j=1}^k g_j(x)y^{(j-1)}\right),$$

$$\mathbf{c} = (c_1, \dots, c_k).$$

So that

$$\mathbf{y}' = \boldsymbol{\phi}(x, \mathbf{y}), \quad \mathbf{y}(a) = \mathbf{c}$$

where \mathbf{y} ranges over a k-cell R.

(2) To show that the problem has at most one solution, by Exercise 5.28 it suffices to show that there is a constant A such that

$$|\phi(x, \mathbf{y}) - \phi(x, \mathbf{z})| \le A|\mathbf{y} - \mathbf{z}|$$

whenever $(x, \mathbf{y}) \in R$ and $(x, \mathbf{z}) \in R$.

(3) Since all g_j $(1 \le j \le k)$ are real continuous functions on a compact set [a,b], all g_j are bounded (Theorem 4.15), say $|g_j| \le M$ on [a,b] for some $M_j \in \mathbb{R}^1$ $(1 \le j \le k)$.

(4) Write
$$\mathbf{y} = (y_1, \dots, y_k)$$
 and $\mathbf{z} = (z_1, \dots, z_k)$. So

$$\begin{aligned} &|\phi(x,\mathbf{y}) - \phi(x,\mathbf{z})|^{2} \\ &= \left| \left(y_{2} - z_{2}, y_{3} - z_{3}, \dots, y_{k-1} - z_{k-1}, -\sum_{j=1}^{k} g_{j}(x)(y_{j} - z_{j}) \right) \right|^{2} \\ &= \sum_{j=2}^{k-1} (y_{j} - z_{j})^{2} + \left(-\sum_{j=1}^{k} g_{j}(x)(y_{j} - z_{j}) \right)^{2} \\ &\leq \sum_{j=2}^{k-1} (y_{j} - z_{j})^{2} + \sum_{j=1}^{k} g_{j}(x)^{2} \sum_{j=1}^{k} (y_{j} - z_{j})^{2} \\ &\leq \sum_{j=2}^{k-1} (y_{j} - z_{j})^{2} + \sum_{j=1}^{k} M_{j}^{2} \sum_{j=1}^{k} (y_{j} - z_{j})^{2} \\ &\leq \sum_{j=1}^{k} (y_{j} - z_{j})^{2} + \sum_{j=1}^{k} M_{j}^{2} \sum_{j=1}^{k} (y_{j} - z_{j})^{2} \\ &\leq \left(1 + \sum_{j=1}^{k} M_{j}^{2} \right) |\mathbf{y} - \mathbf{z}|^{2}. \end{aligned}$$

$$(31)$$

Hence $|\phi(x, \mathbf{y}) - \phi(x, \mathbf{z})| \le A|\mathbf{y} - \mathbf{z}|$ for some $A = \left(1 + \sum_{j=1}^k M_j^2\right)^{\frac{1}{2}}$.
